

lecture 1

use virtual environment

coding environment for exam: jupyter notebook

types: int, float, complex, bool

membership operator: in

string formatting:

strip()

find()

split()

join()

f string

function

type annotation

eg.

```
def add-c (first: tuple, second: tuple) => tuple
    return complex:
```

sequence unpacking

x values

lambda

function and lambda expressions behave

like any other variable of a function, it means it can be passing around functions

dictionaries

- dict(), {}

- ordered by the time the key was first written

- update,

- unpacking it by using ** operator

set

- set(), {}

- unordered, unique, mutable, unhashable, cannot be used as keys

conditional expressions

if, elif, else

return "same" if x==y else "different"

iterables

iter()

next()

for i in range(5):

break : immediately exit a loop

continue : jumps to the next iteration

enumerators

wraps an iterable

generate a tuple with index and the element

eg.

```
for n, tag in enumerate(['yes', 'no'])
    ...
```

Generators:

yield

reading data from a file:

```
with open('path', 'r') as fd:
```

```
    data = []
```

```
    for l in fd:
```

```
        ...
```

```
        data.extend(lst)
```

writing result back into a file

example code in teaching code
